Galivelop-workflow for your team

Español

A workflow for coding with AI agents (Claude Code first), drawn from real projects: **skills, hooks, scripts and templates** installed in your repository that enforce the rules instead of trusting the agent to remember them.

What it solves

- **Sessions end:** the log `docs/handoff.md` and the `Siguiente:` (next step) trailer of every commit let the next session carry on without asking.
- **What the agent calls done is not always done:** the `pre-push` runs your check on the exact commit being pushed, and the protected branch requires a review mark tied to that commit (`reviewed.sh`).
- **Token spend grows unmeasured:** `gw-selector` picks the skill and model per task, `gw-orchestrate-dealer` deals work out to clean-context subagents and `gw-opt-tokens` measures where the spend went.

What gets installed

Piece	What it does
Git hooks	`pre-commit` (secrets), `commit-msg` (format and traces), `pre-push` (check, private data, review)
Claude Code hooks	State at start, no ending without pushing, review before a PR, subagent cap
Skills	26, in the open Agent Skills format: 11 of its own (`gw-*`) and 15 by Matt Pocock
Scripts	Deterministic, in Python 3.8+ and bash 3.2: `apply.py` , `doctor.py` , `check.sh` , `handoff.py` , `version.py` ...
Configuration	A single file, `.claude/gw.json` : language, check, protected branch, what is content and what is code

Everything lives **inside your repository** (`.claude/gw/` , `.claude/skills/` , `.githooks/`), so it also works in cloud sessions that do not load plugins.

How to apply it

1. Requirements: `git` , `bash` and `python3` 3.8 or later (on Windows, Git Bash or WSL).
2. In Claude Code, `/gw-init` : the agent decides with you what needs judgement and `apply.py` copies and configures.
3. `/gw-doctor` checks it is set up right and gives the command that fixes each failure.
4. `/gw-update` brings the project to each new version and shows the changes before applying them.

The hooks **fail closed** when a piece of data is missing, and the repo itself passes more than a thousand tests on Linux and macOS.
