How Galivelop works with AI agents

Español

Galivelop builds software with coding agents (Claude Code) following **Galivelop-workflow**: its own public, versioned method, where the rules do not rely on the agent's good will but on **automatic checks that enforce them**.

What it solves for your project

- **Continuity.** An AI session can stop at any time; the work is not lost. Everything is pushed to the repository at every stable point, with a log that says where it stands and what comes next.
- **Quality.** Nothing reaches the published version without a code review, green tests and your confirmation.
- **Controlled cost.** Each task uses the AI model it calls for, and the spend is measured instead of guessed.
- **Traceability.** Every change can be followed from the plan's task to the commit that made it.

How the work runs

1. **Plan and tasks.** The work is split into tasks with an id, in a plan you can read.
2. **Work on a branch.** The agent works away from the published version and pushes often, with the log updated in the same commit.
3. **Continuous checking.** Every push runs the project's check (tests, format, private data) on the exact code being pushed.
4. **Review before release.** Code review, a process retrospective and a review mark tied to that code.
5. **Release with your approval.** The published version only changes when you confirm it.

What it guarantees, and how

Guarantee	What enforces it
Nothing is lost between sessions	Constant pushes; a hook does not let a session end with unpushed work
Nothing unreviewed is released	A review mark tied to the commit; without it, the push is rejected
Tests really prove something	A new test has to fail without its fix
No keys or private data leak	A secrets check on every commit and every push
A CI that does not start is not green	It counts as red and you are told
Every change is traceable	Commit format with the task id and the next step

What you get

Your repository, with its full history and the log; the plan with the state of each task; and every version with its list of changes. The method is public: you can review it at github.com/Zeldris/Galivelop-workflow.
